NVIDIA Corporation NVDA

High returns on capital, priced as if growth will fade faster than we model

OVERWEIGHT

$270.37 target · 12m

Price (2026-07-08)	$204.12
12m total return	+32%
Fair value today	$237.66
Confidence	High

We rate **NVIDIA Corporation OVERWEIGHT** with a 12-month price target of **$270.37**, **+32%** from the $204.12 share price. The target starts from our blended fair value of $237.66 a share, rolls it forward a year at the 11.5% cost of equity, deducts $0.04 of dividends and gives the Street consensus a 15% weight as a deliberate hedge against model error.

Investment summary

NVIDIA Corporation generated **$215.94bn** of revenue in FY2026, +65% on the year, at a **60.4%** EBIT margin (exceptional). Over the 3-year window revenue compounded at 100.0% a year, but not smoothly: growth ranged from +65% in FY2026 to +126% in FY2024 and the EBIT margin from 21% to 62%, which is why we handle the earnings base with care. Consensus looks for revenue of $554.44bn in FY2027 (+157%) and EPS of $12.76.

At $204.12 the shares trade on **16.0x** NTM earnings against a 21.0x reference for semiconductors (-24%) and on 13.5x EV/EBITDA against 15.0x (-10%). Three lenses feed the fair value, ranging from $197.13 to $283.20 (dispersion 15%).

The Street's mean 12-month target is $301.62 (+48%). Our model-only target of $264.86 sits 12% below it; the published number blends the two so that neither a model error nor a consensus drift dominates.

The Reloj de inversión reads **Estanflación** (Stagflation) with weak conviction; Semiconductors has a probability-weighted tilt of **-0.9 pp** a year against the US market. The cycle is context for the call, not an input to the target (page 11).

A reverse DCF shows the price discounts year-one revenue growth of **157%** against our 157% base, so the market is asking for more than we model. That is the cleanest single measure of how demanding the price is.

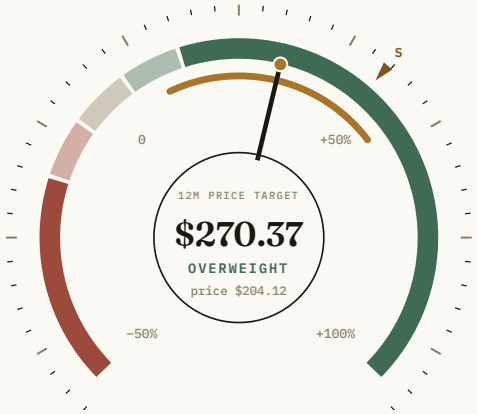

Key risks

- Estimate risk: consensus forecasts can be revised sharply, and the forward-multiple lenses move one-for-one with the earnings they are applied to.
- Multiple risk: target multiples are anchored on sector medians; a de-rating of the peer group lowers the target regardless of company performance.
- Single third-party data source: restatements, non-recurring items or classification differences can shift the output.

WHAT WOULD CHANGE OUR MIND

- A sustained miss on FY2027 revenue (consensus +157%) or on the EBIT margin path; each 100bps of margin is worth $3.31 a share in the DCF.
- A re-rating of the sector multiple the relative lenses are anchored on, in either direction.
- A move in the cost of equity from today's 11.5%: rates and the equity risk premium are the largest single swing factor in the DCF.
- A change in the Reloj's phase reading that turns the sector's historical tilt from headwind to tailwind, or the reverse.

INVESTMENT THESIS

Why this number, and what it rests on

+32% to a $270.37 target rests on earnings power, a valuation below fair value and a balance sheet that removes financing risk.

1 · Earnings power and returns on capital

Consensus has revenue growing **+157%** in FY2027; our DCF fades growth from 157% in year one to the 2.5% terminal rate over 10 years, so no single year's step is extrapolated. The business earns **104.6%** on invested capital against a 11.4% cost of capital, a spread of 9,319bps that means growth creates value.

Margins have been volatile (standard deviation 16.9% across the window), which limits how much of the current profitability the DCF can treat as permanent.

Return history. ROIC has run 23% → 103% → 153% → 105% over the window, so today's 105% is a recovery from a trough rather than a steady state: the thesis needs it to hold. The WACC we compare it with is 11.4%.

2 · Valuation

Our three lenses blend to **$237.66** today, 16% above the price; the heaviest, discounted cash flow (fcff), carries 39% of the weight at $197.13.

At our target the stock would trade on **21.2x** NTM earnings against 21.0x for the sector, i.e. a premium that we think is defensible given its growth and returns.

3 · Balance sheet and cash conversion

NVIDIA Corporation ends FY2026 with $62.56bn of cash against $11.04bn of debt, a **net cash** position of $51.52bn. Free cash flow (operating cash flow less capex) was $96.68bn, a 2.0% yield on the market cap, and capex ran at 2.1x depreciation.

Quality screens. The accounting screens give a Piotroski F-score of 4 out of 9, an Altman Z of 64.6 (safe zone) and Sloan accruals of 10.9%, so we lean harder on cash flow than on reported profit. Page 8 has the detail.

What the price discounts, and where we differ from the Street

Solving the DCF backwards for the current price gives year-one revenue growth of **157%** (terminal growth 2.7%) against our 157% base. The market therefore already needs more than we forecast; delivery at our base case would not be enough to justify the price on the DCF alone.

Against a Street mean of $301.62 (+48%), our model-only target of $264.86 is 12% lower. We flag the gap rather than close it: where the model is right the stock has an information edge, where it is wrong the Street's inputs deserve more weight.

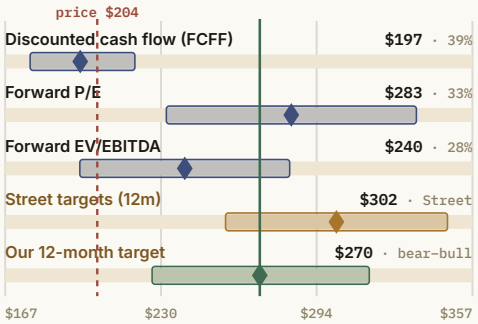

KEY TAKEAWAYS

- OVERWEIGHT: $270.37 target (+32%), $237.66 fair value, 11.5% cost of equity.
- Consensus revenue +157% in FY2027; EBIT margin 60% today, 60% in our terminal year.
- 16.0x NTM P/E against 21.0x for the sector; 21.2x at our target.
- Cycle: Stagflation (weak signal), sector tilt -0.9 pp a year.

The Reloj de inversión reads **Estanflación** (Stagflation) with weak conviction; Semiconductors has a probability-weighted tilt of **-0.9 pp** a year against the US market. Pages 11 and 12 set out the evidence behind that reading.

Priced like the sell-side prices it: a target multiple on forward earnings and EBITDA (peer-anchored, adjusted for growth and earnings durability), cross-checked against a 10-year FCFF DCF whose growth decays and whose margins mean-revert.

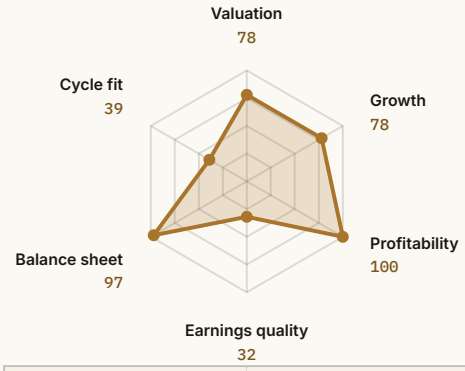

EXHIBIT 5 VALUE PER SHARE BY LENS

VALUATION · METHOD

How $237.66 of fair value becomes a $270.37 target

Several independent answers to "what is a share worth?", weighted by what fits the business, filtered by explicit guardrails.

Priced like the sell-side prices it: a target multiple on forward earnings and EBITDA (peer-anchored, adjusted for growth and earnings durability), cross-checked against a 10-year FCFF DCF whose growth decays and whose margins mean-revert. The profile for **NVDA** is **Standard (forward multiples + DCF)**; it prescribes four methods, of which three produced a usable value.

The lenses, one by one

Discounted cash flow (FCFF) ($197.13 a share, 39% of the weight) values ten years of free cash flow to the firm at a 11.44% WACC with 2.50% terminal growth; the terminal value is $2,207.67bn (47% of EV). Growth decays geometrically and margins mean-revert, so it is deliberately conservative where the multiples lenses are generous.

Forward P/E ($283.20 a share, 33% of the weight) applies a **22.2x** target multiple to NTM EPS of $12.76. The multiple starts from an anchor of 21.0x (Semiconductors reference 21.0x (no usable peer set)), is scaled ×1.06 for durable growth (14.0% durable growth vs 12.0% sector).

Forward EV/EBITDA ($239.77 a share, 28% of the weight) capitalises NTM EBITDA of $363.08bn at **15.9x**, then bridges to equity through net cash. The anchor is 15.0x; growth and durability adjustments follow the same logic as the P/E lens, which makes it a capital-structure-neutral cross-check.

What the dispersion tells us. The lenses span $197.13 to $283.20, a 1.4x spread (coefficient of variation 15%). Agreement among independent methods is the strongest evidence a valuation can offer; here it is broad.

Weights. The profile starts from dcf 35%, pe fwd 30%, ev ebitda fwd 25% and ddm 10%. After the guardrails and the lenses that could not be built are removed, the weights are renormalised over those that remain, which is why they differ from the profile's starting point.

Guardrails: what the model is not allowed to do

Every intervention is explicit. A lens outside 0.2×–5× the share price is excluded (or winsorised if it is the only one); a lens more than 2.2× away from the median of the others is down-weighted by 60%; the published target is confined to 0.4×–2.5× the price; and with fewer than two usable lenses, or a result forced by a guardrail, the company is published NOT RATED rather than given a number we cannot defend.

- Target anchored 15% to the Street consensus ($301.62); model-only target $264.86.

From fair value to target

Fair value today $237.66 × (1 + 11.46% cost of equity) − $0.04 dividends = **$264.86** model target; the Street mean of $301.62 at 15% weight moves it to **$270.37**.

Confidence is graded **High**: 3 independent lenses agree on a valuation; lens dispersion is tight (CV 15%); model target is within 25% of the Street.

Bear and bull values are the low and high ends of the lens ranges (the DCF's own bear and bull scenarios where it is present), rolled forward the same way. They bracket the model's uncertainty; they are not statistical confidence intervals.

VALUATION · RELATIVE

What the multiples say, and what we adjust before using them

Sector and peer anchors, scaled for growth, leverage and the durability of the earnings they are applied to.

On the numbers the market pays today, NVIDIA Corporation looks cheap on earnings (16.0x NTM against 21.0x for semiconductors, -24%) and cheap on enterprise value (13.5x EV/EBITDA against 15.0x).

Where the anchor comes from

There is no usable peer set here (fewer than three peers with valid multiples), so the relative lenses are anchored on the semiconductors reference table: 21.0x P/E, 15.0x EV/EBITDA, 7.0x EV/Sales and 5.0x P/B, with a sector growth rate of 12%. A sector median is a starting point, not a verdict: each lens then adjusts it for the company in front of us.

What we adjust, and why

Growth. The anchor is scaled ×1.06 (14.0% durable growth vs 12.0% sector) — the market pays for growth that lasts, so we use durable earnings growth of 14.0% (historical revenue CAGR (capped at 15%)) rather than a one-year consensus jump.

The result is a target P/E of **22.2x** applied to NTM EPS, worth $283.20 a share.

Cross-checks

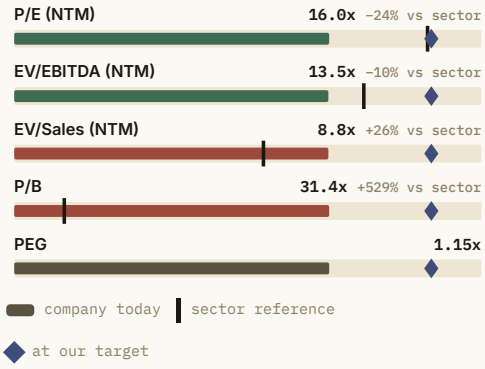

EV/Sales is 8.8x against 7.0x for the sector, price-to-book is 31.4x against 5.0x, free-cash-flow yield is 2.0%, dividend yield is 0.0% and the PEG ratio is 1.15x. These do not enter the target unless a lens is built on them, but they show whether the headline multiple is flattered by one line of the accounts.

Growth-adjusted view. The PEG ratio of 1.15x divides the P/E by durable growth; below 1 the market is paying less than a point of multiple per point of growth. Treat it with caution when growth is a cyclical rebound rather than a trend.

P/E versus EV/EBITDA. The two multiples disagree when capital structures differ. With net cash, enterprise value is lower than market capitalisation, so EV/EBITDA flatters the shares slightly relative to P/E. We use both for that reason.

Relative valuation is only as good as the earnings it is applied to. When forward EPS is far above trailing, a low P/E can be a warning sign rather than a bargain: it is the market declining to capitalise a peak. That is why the next two pages test the earnings base before the cash-flow model is built.

VALUATION · SCENARIOS AND SENSITIVITY

Range of outcomes, and the levers that move them

Bear, base and bull cases built from the lens ranges and the DCF scenarios, with the DCF's two most important dials.

We weight three outcomes 25 / 50 / 25: a **bear** case of $226.46, a **base** case of $270.37 and a **bull** case of $314.99. The probability-weighted target is **$270.55** (+33% including dividends), close to the base case because the range is roughly symmetric.

What each case needs to be true

Bear. The DCF's bear scenario values the shares at $176.75: slower revenue, margins that revert faster toward the through-cycle level and a higher reinvestment burden. Even then the downside to $226.46 is +11% from today's price, which is where the lenses' lower ends cluster.

Base. Consensus for the near years, growth fading geometrically to 2.5%, margins mean-reverting from 60% toward 60%, and a 11.4% WACC: $197.13 a share on the cash-flow lens, $237.66 once the multiples lenses are blended.

Bull. The DCF's bull scenario reaches $219.42: growth that fades more slowly and margins that hold closer to today's level. Our bull target of $314.99 (+54%) is the upper end of the lens ranges rolled forward.

How sensitive is the DCF?

Across a ±150bps range of WACC and ±100bps of terminal growth the DCF value per share runs from $162.43 to $256.79 (Exhibit 22). The cost of capital matters more than terminal growth: each 75bps of WACC moves the value by about $16.88 (9%), against $5.11 for 50bps of terminal growth.

Risk and reward

The price sits below even our bear case ($226.46), which means every scenario we run is above today's price. We would treat that as a prompt to test whether the bear case is conservative enough rather than as free money.

Stress tests

Shocking one input at a time to the DCF, the most damaging are **revenue growth −20% (relative)** (-20%) and WACC +100bps (-10%); the most helpful are revenue growth +20% (relative) (+23%) and WACC −100bps (+13%) (Exhibit 24). Only revenue growth +20% (relative) lifts the DCF to the blended fair value on its own.

How sensitive is the multiple-based value?

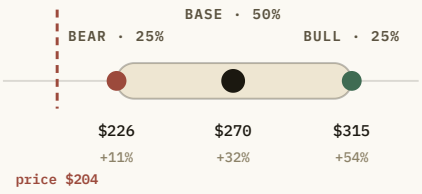

Forward earnings and the target multiple are the inputs that matter most. A 10% error in NTM EPS moves the forward P/E value by about $28.33 a share, and a 10% change in the target multiple by $28.33; across the grid (Exhibit 23) the value runs from $181.29 to $407.91.

What each lever is worth

- **Cost of capital:** every 75bps of WACC moves fair value by ≈$16.88/share (9%). Rate path and the equity risk premium are the single biggest swing factor.
- **Terminal growth:** 50bps of perpetuity growth is worth ≈$5.11/share — the market's read on the company's long-run competitive position.
- **Operating margin:** each 100bps of EBIT margin across the forecast is worth ≈$3.31/share — watch pricing power, mix and cost discipline in quarterly prints.
- **Top-line delivery:** our base assumes 156.8% year-one growth fading to 2.5%; sustained beats/misses versus that glide path are the cleanest re-rating trigger either way.

The sensitivity table is shaded against the current price (green above, terracotta below): when every cell is one colour the DCF has a clear view; when the base case sits near the edge of a colour change, the conclusion depends on the discount rate.

EXHIBIT 20 BEAR, BASE AND BULL TARGET

Source: SuperAnalyst valuation model.

EXHIBIT 21 SCENARIO TABLE

CASE	PROB.	TARGET	RETURN	DCF
Bear	25%	$226.46	+11%	$176.75
Base	50%	$270.37	+32%	$197.13
Bull	25%	$314.99	+54%	$219.42

Weighting bear / base / bull 25 / 50 / 25 gives **$270.55** (+33% incl. dividends). Bear and bull come from the lens ranges (DCF bear/bull cases in the last column).

FINANCIAL ANALYSIS · GROWTH AND PROFITABILITY

Growth, margins and earnings

Revenue 100.0% a year over 3 years; the EBIT margin is the swing factor.

Revenue went from $26.97bn in FY2023 to **$215.94bn** in FY2026, a compound rate of **100.0%** a year. The path was anything but linear (FY2024 +126%, FY2025 +114%, FY2026 +65%): a swing of 60 points in annual growth is the signature of a business whose revenue follows a cycle in pricing or volumes rather than a steady compounding base.

Top line

Consensus looks for revenue of **$554.44bn** in FY2027 (+157%). Our DCF takes consensus for the first two years and then lets growth decay geometrically toward the 2.5% terminal rate, so revenue reaches $1.06trn by year 10 (17.3% a year over the period). Large numbers compress growth and competition erodes it; we do not extrapolate any single year.

Margins

The EBIT margin was **60.4%** in FY2026, exceptional by sector standards, within a FY2023–FY2026 range of 21% (FY2023) to 62% (FY2025). Gross margin stood at 71.1% (from 57% at the start of the window), and net margin at 55.6%. The DCF takes the margin from 60% to a peak of 64% and a terminal 60%.

The margin is the most valuable single input after the discount rate: each 100bps of EBIT margin across the forecast is worth about **$3.31** a share in the DCF.

Earnings per share

Diluted EPS was $4.90 in FY2026 (FY2023 $0.17, FY2024 $1.19, FY2025 $2.94 before). Consensus has **$12.76** for FY2027, which blends to **$12.76** on a next-twelve-months basis. That NTM figure is **5.5x** the $2.30 the business has earned on average through the cycle, so we capitalise it at a multiple scaled by 1.00: the market does not pay a full multiple for earnings that are a multiple of normal.

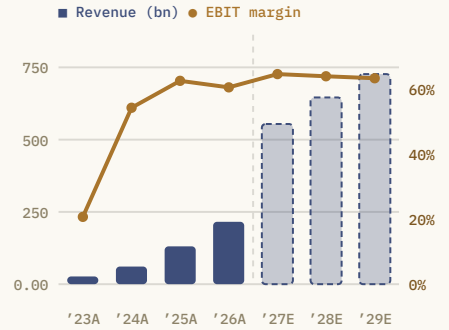

Operating leverage. Last year each extra $1 of revenue brought $0.57 of EBIT (below the 60% average margin), which says growth came with lower incremental profitability.

The table below the text sets out the income statement; forecast columns (shaded) are consensus where it exists and our DCF base case otherwise. Any line a provider does not report is shown as a dash rather than estimated.

WHAT TO WATCH

- FY2027 revenue against the $554.44bn consensus path.
- The EBIT margin against the 60% terminal level our DCF assumes.
- Gross-margin direction: it separates pricing power from volume.

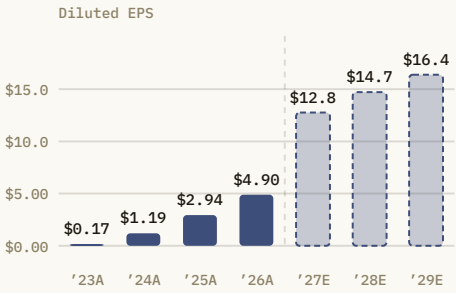

EXHIBIT 25 REVENUE AND EBIT MARGIN

Revenue compounds **+50%** a year to FY2029E on the base case; EBIT margin 60% → 63%.

Forecast columns: revenue, EBIT and capex are the DCF base case; net income and EPS use consensus where it covers the year; free cash flow in forecast years is unlevered (FCFF). Dashes mean the provider does not report the line.

Source: SuperAnalyst valuation model; Yahoo snapshot as of 2026-07-08; analyst consensus. Methodology and disclosures on page 15.

FINANCIAL ANALYSIS · CASH FLOW AND BALANCE SHEET

Cash generation, capital intensity and the balance sheet

Free cash flow of $96.68bn; net cash; ROIC 105% vs WACC 11.4%.

Operating cash flow of $102.72bn funded $6.04bn of capex in FY2026, leaving free cash flow of **$96.68bn** — 0.9x net income and a 2.0% yield on the market capitalisation.

Capital intensity

Capex ran at **3%** of sales (from 7% in FY2023), 2.13x depreciation and amortisation. Above 1x the company is investing for growth, so free cash flow trails earnings until that spending matures; our DCF converges capex to 1.10x D&A by the terminal year so that growth is funded without permanent over- or under-investment.

Cash conversion

Operating cash flow was 0.86x net income, below earnings, which is worth watching: profit is not yet turning into cash; Sloan accruals of 10.9% of assets point the same way. On free cash flow the shares yield 2.0%, and the 0.0% dividend is well covered by it.

Balance sheet

NVIDIA Corporation holds **$62.56bn** of cash and short-term investments against $11.04bn of debt: a net cash position of $51.52bn. EBIT covers interest 503.4x, which our credit screen maps to AAA; the current ratio is 3.91x. Shareholders' equity is $157.29bn, 31.4x book at the current price.

Returns on capital

ROIC is **104.6%** against a 11.4% WACC, a spread of +9,319bps; ROE is 76.3% and ROA 58.1%. Over the window ROIC moved 23% → 103% → 153% → 105%, so today's return is not a straight line either. The DuPont split for FY2026 is a 55.6% net margin × 1.04x asset turnover × 1.31x equity multiplier = 76.3% ROE: returns come from profitability, not from leverage.

Working capital. The cash conversion cycle is 133 days (receivables 65, inventory 125, payables 57). In a growth phase that cycle consumes cash; if growth slows, the same cycle releases it, which is part of why free cash flow can run ahead of earnings in a downturn.

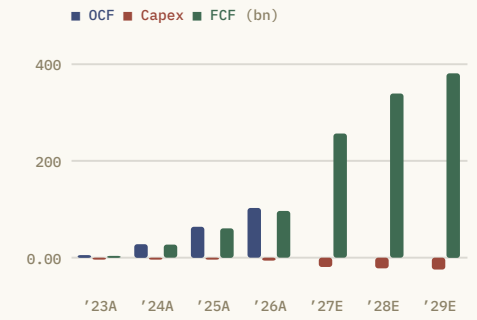

Capital return. The dividend is $0.04 a share (0.0% yield). Buybacks are not captured in the data we use, so total shareholder yield may be higher.

Statements are shown on page 14; forecast cash flow is unlevered (free cash flow to the firm) so that it can be discounted at the WACC without double-counting the interest tax shield.

KEY TAKEAWAYS

- Free cash flow $96.68bn; 0.9x net income.
- Net cash balance sheet.
- ROIC 105% against a 11.4% WACC.

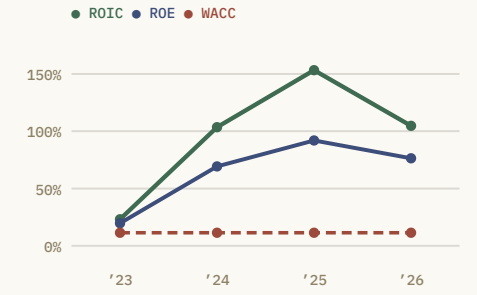

EXHIBIT 29 CASH GENERATION

FCF +96.7bn last year, 0.8x net income; capex intensity 2.1x D&A.

FINANCIAL ANALYSIS · EARNINGS QUALITY

Earnings quality and financial health

Are the reported numbers backed by cash, is the balance sheet safe, and is the earnings base durable?

Accounting-based screens give a Piotroski F-score of **4** out of 9 testable, an Altman Z of **64.6** (safe) and Sloan accruals of **10.9%** of assets. Taken together the signals are mixed, so we lean harder on cash-flow evidence than on reported earnings.

Piotroski F-score

The score counts nine binary tests of profitability, leverage and efficiency. NVIDIA Corporation passes four — positive return on assets, positive operating cash flow, leverage falling and no dilution (share count not up); it fails return on assets improving, cash flow exceeds net income (low accruals), current ratio improving, gross margin improving and asset turnover improving.

The failures are worth reading in context: a falling current ratio or a higher share count are typical of a company that is funding rapid growth, not of distress.

- **Profitability**: 2 of 4 passed
- **Leverage and liquidity**: 2 of 3 passed
- **Efficiency**: 0 of 2 passed

Distress risk

Altman's Z-score combines working capital, retained earnings, operating profit, market value of equity relative to liabilities and sales to assets. At **64.6** NVIDIA Corporation sits in the safe zone (above 2.99 is safe, below 1.81 is distress). A score this high is helped by a large market capitalisation relative to liabilities, so it mainly confirms the absence of balance-sheet stress rather than measuring quality of earnings.

Accruals and the cash cycle

Sloan accruals — net income less operating cash flow, scaled by assets — are 10.9%. Readings below zero mean earnings are more than backed by cash; strongly positive readings are the classic marker of aggressive accounting. Working capital runs on DSO 65 days, DIO 125 days, DPO 57 days, a cash conversion cycle of 133 days. A cycle of that length ties up cash as the company grows, which is why the DCF charges 14.4% of incremental revenue to working capital.

Is the earnings base durable?

Yes, on the evidence available. Revenue and margins show no peak-to-trough pattern in the reported history, so forward earnings are capitalised at the full target multiple (durability factor 1.00); growth source: historical revenue CAGR (capped at 15%).

Scorecard. Of six factors scored 0–100, profitability (100) is the strongest and earnings quality (32) the weakest; the scales are given in the appendix.

KEY TAKEAWAYS

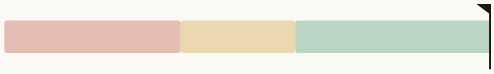

- Piotroski 4/9, Altman Z 64.6 (safe).
- Accruals 10.9% of assets: watch the gap between profit and cash.
- No durability haircut applied.

EXHIBIT 34 PIOTROSKI F-SCORE: 4 OF 9

VALUATION · DISCOUNTED CASH FLOW (1/2)

DCF: the assumptions behind the cash flows

Consensus for the near years, then geometric growth decay, mean-reverting margins and reinvestment tied to growth and returns.

The DCF is the cross-check that ignores what other investors pay. It values **10 years** of unlevered free cash flow plus a terminal value, discounted at the **11.44%** WACC. The early years follow consensus; thereafter growth decays geometrically and margins mean-revert, so the model cannot extrapolate a single strong year.

The drivers

Revenue growth (156.8% → 2.5% over 10y) — Year 1 follows consensus revenue for FY2027. Growth then decays geometrically from 22.0% to the 2.5% terminal rate as revenue compounds toward $1,065bn — competitive entry and the law of large numbers compress incremental growth; no single year's step is ever extrapolated.

EBIT margin (60.4% → 64.5% → 59.9% (compresses)) — Reported margin is 60.4%; year-1 margin is 64.5%. This is a compounder, so we revert only 30% of the way toward the through-cycle average of 49.4%, landing at 59.9% — crediting some but not all of current profitability as durable.

Reinvestment (capex) (3.5% → 3.0% of sales) — Starts at the historical capex intensity (3.5%) against D&A of 2.7%, converging to 1.10x D&A by the terminal year — a steady state that funds growth without permanent over- or under-investment.

Working capital (14.4% of Δrevenue) — Incremental working capital absorbs 14.4% of each year's revenue increase (historical median) — a cash drag as the business scales.

Tax rate (13.5%) — Normalised to the trailing effective rate of 13.5%, applied to EBIT to derive NOPAT.

Terminal growth (2.5%) — At or below long-run nominal GDP (4.0%); a mature going concern cannot outgrow the economy in perpetuity. Terminal reinvestment is g/ROIC.

Cost of capital

The cost of equity is **11.46%**: a 4.3% risk-free rate plus a beta of **1.56** times a 4.6% equity risk premium. The beta is blended: 50% Blume-adjusted regression, 50% industry bottom-up. Debt costs 4.9% before tax (AAA (EBIT/int = 503.4x)), 4.2% after tax, and makes up 0.2% of the capital structure at market values, so the WACC is 11.44%.

Terminal value

Terminal growth is **2.5%**, at or below long-run nominal GDP, with terminal reinvestment of g ÷ ROIC (2% of NOPAT at a 106% terminal ROIC). The terminal value is **47%** of enterprise value.

VALUATION · DISCOUNTED CASH FLOW (2/2)

DCF: what it values, and what the price requires

$197.13 a share on the cash-flow lens; the terminal value carries 47% of enterprise value.

The base case gives an enterprise value of **$4.72trn** and an equity value of **$4.77trn**, or **$197.13** a share (-3% against the price). That is the lowest of our lenses, and the triangulation weights it accordingly.

Where the value sits

Explicit cash flows contribute $2.52trn and the terminal value $2.21trn (47% of EV). The terminal value implies an exit multiple of **9.3x** EBITDA against 33.8x today, a far lower multiple than the market pays now, which is where much of the gap to the multiples lenses comes from.

Terminal ROIC is 105.9% against a 11.4% WACC, so growth in perpetuity still creates a little value; if returns fell to the cost of capital the terminal value would be worth less than shown.

Why the DCF can sit below the multiples

Multiples capitalise consensus earnings as they are; the DCF has to earn them. Neither answer is wrong; the gap measures how much of today's profitability the market is treating as permanent.

Reverse DCF: what the price needs

Holding our cost of capital and long-run assumptions, the current price requires year-one revenue growth of **157%** (terminal growth 2.7%) against our 157%. The market is therefore already pricing in more than we model; the shares need delivery above our base case to earn their cost of equity on this lens.

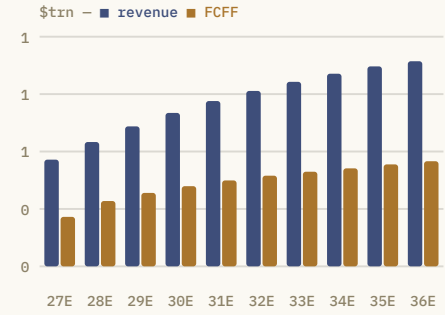

Implied multiples. At the DCF value of $197.13 the shares would trade on 15.4x NTM EPS, against 16.0x today and 21.0x for the sector. That is a useful sanity check: a DCF that implies a multiple far below any peer is usually telling us about its own conservatism as much as the stock.

Model diagnostics

- Terminal EV/EBITDA vs today: 9.3x implied vs 36.7x current — ok
- Terminal ROIC vs WACC: 105.9% vs 11.4% — ok

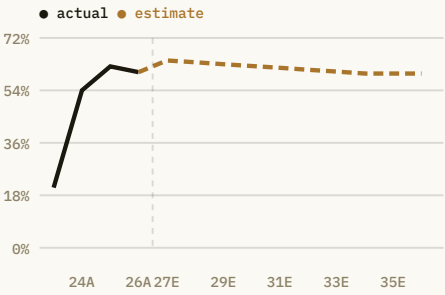

The bear and bull scenarios bracket the base value at $176.75 and $219.42; the sensitivity table on page 5 shows the effect of the discount rate and terminal growth.

MACRO CONTEXT · RELOJ DE INVERSIÓN

Where the cycle is: Estanflación (Stagflation), weak signal

Growth and inflation read from 28 FRED series, expressed as probabilities of four phases rather than a single label.

The Reloj de inversión — our own cycle model, published as a separate project — classifies the US economy each month into one of four phases from growth and inflation. Its latest reading (2026-10) is **Estanflación** (Stagflation) with **weak** conviction: 37% against 36% for Overheat.

How the Reloj reads the cycle

Twenty-eight FRED series are converted to robust z-scores and combined by principal components into a growth axis and an inflation axis; the month's position on that plane, and its uncertainty, give a probability for each phase. A phase is Recovery (growth above trend, inflation below), Overheat (both above), Stagflation (growth below, inflation above) or Reflation (both below).

The current reading

Growth sits at **-0.01σ** and inflation at **+0.19σ** of their ten-year norms, i.e. close to the centre of the plane, where phase calls are least reliable. Over three months growth has moved -0.04σ and inflation -0.07σ. The model's 12-month recession probability is **8%**.

Why a weak signal changes how we use it

Only 1.1 percentage points separate the first and second phase. When the call is that close, naming one phase and acting on it would be false precision; the more honest estimate is the probability-weighted one. That is what we use in the next section: each phase's historical sector return, weighted by today's phase probabilities.

What each phase has favoured

The Reloj's rotation playbook, built from the same history (inverse volatility), leans on different sleeves in each phase:

- **Recovery**: Consumer staples (22%), Health care (21%) and Materials (20%)
- **Overheat**: Consumer staples (42%), Financials (34%) and Energy (24%)
- **Stagflation**: Utilities (32%), Industrials (26%) and Semiconductors (22%)
- **Reflation**: Gold miners (20%), Consumer staples (18%) and Health care (18%)

How long in this phase. The Reloj has called Estanflación for three consecutive months, and for 68% of the last 8 years. A phase that has just changed carries more uncertainty than one that has persisted.

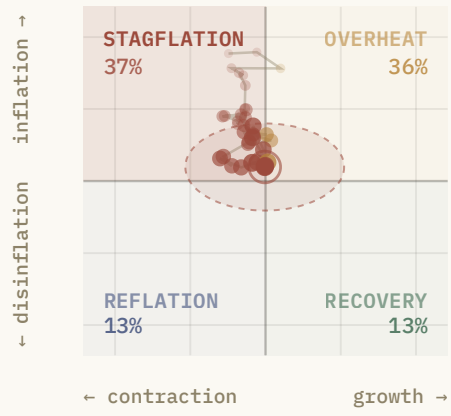

The macro read is context for the valuation. It does not move our price target, but it does tell us whether the sector a company belongs to has historically had the wind at its back or in its face.

Direction of travel. A year ago the Reloj plotted at growth -0.56σ and inflation +0.34σ; it now plots at -0.01σ and +0.19σ, a drift toward stronger growth and little change in inflation.

KEY TAKEAWAYS

- Estanflación (Stagflation), weak signal: 37% vs 36% for Overheat.
- Growth -0.01σ, inflation +0.19σ; 12-month recession probability 8%.
- We weight phases by probability; the label alone is not a forecast.

MACRO CONTEXT · SECTOR EVIDENCE

What the Semiconductors sleeve has paid in each phase, and where that leaves us

Excess returns against the US market by phase, shrunk toward zero, with the statistics that say how much to trust them.

We map **NVIDIA Corporation** to the Reloj's **Semiconductors** sleeve, which it tracks through SOXX and SMH; the Reloj's evidence for Semiconductors runs back to 1970 and covers 226 months in its longest phase.

What the sector has paid in each phase

- **Recovery**: 15.2% a year on average, +1.9 pp a year versus the US market (t = +0.7, hit rate 57%, no-signal evidence)
- **Overheat**: 8.9% a year on average, -0.9 pp a year versus the US market (t = -0.3, hit rate 48%, no-signal evidence)
- **Stagflation** (current): 1.8% a year on average, -3.4 pp a year versus the US market (t = -1.3, hit rate 56%, weak evidence)
- **Reflation**: 22.6% a year on average, +3.6 pp a year versus the US market (t = +1.4, hit rate 60%, weak evidence)

Read these with the statistics in mind. A t-statistic below about 2 means the sector's return in that phase cannot be told from chance; across all sector × phase cells the Reloj tests, only 25 of 192 survive false-discovery control. That is why the Reloj shrinks every estimate toward zero, and why we quote the shrunk figure.

The probability-weighted tilt

Weighting each phase's shrunk excess return by today's phase probabilities gives a tilt of **-0.9 pp** a year for Semiconductors against the US market. That is small relative to the noise in the estimates: a nudge, not a thesis.

Scenario: the cycle tips. If the Reloj's runner-up, Overheat, took over, the sector's historical edge would move from -3.4 pp to -0.9 pp a year. Across the four phases Semiconductors has done best in Reflation (+3.6 pp) and worst in Stagflation (-3.4 pp).

Playbook and ETF exposure

In the current phase the Reloj's playbook allocates **22.2%** to Semiconductors. NVDA is the largest holding of the sector ETF, with a 15.26% weight. Owning the sector through its ETF carries that exposure at the weight shown; owning the stock adds single-name risk the sector evidence does not measure.

Putting the cycle and the valuation together

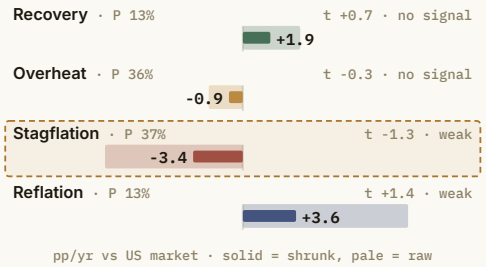

Valuation points up (+32% expected return) while the cycle's historical tilt is a modest headwind (-0.9 pp a year). We read that as a reason to size positions with care and to watch the phase reading, not as a reason to override the valuation.

KEY TAKEAWAYS

- Semiconductors tilt -0.9 pp a year, probability-weighted; current-phase edge -3.4 pp.
- Playbook weight 22.2% in Stagflation.
- Context for the valuation, not an input to the target.

Source: Reloj de inversión, github.com/Perez849/reloj-inversion. The tilt describes historical behaviour; it is not an input to the target and not investment advice.

FACTORS, CATALYSTS AND RISKS

What moves the stock, and what could go wrong

Exposure scored from the model's sensitivities and the company's history; levers quantified in value per share.

We scored eight macro and company-specific factors from the model and the reported history. **High exposure**: interest rates / discount rate, economic cycle / demand and pricing power / margin stability. **Medium**: capital intensity. **Low**: inflation / input costs, credit & refinancing, competitive erosion and execution vs expectations.

What moves the stock most

Interest rates / discount rate (high). Long-duration cash flows: the further out the value sits (terminal-heavy), the more a shift in rates or the equity risk premium re-prices the stock, independent of operations. Evidence: 75bps of WACC ≈ $16.88/sh (9%); TV = 47% of EV.

Economic cycle / demand (high). Historical top-line dispersion is the cleanest read on cyclicality: a stable compounding base decouples from GDP; a volatile one imports the macro cycle into earnings. Evidence: Revenue growth volatility σ = 26.2% over 3y.

Pricing power / margin stability (high). Stable margins across cycles are the fingerprint of pricing power; wide swings say the company is a price-taker whose profitability belongs to the environment, not the franchise. Evidence: EBIT margin σ = 16.9% (range 21%–62%).

What each lever is worth

- **Cost of capital:** every 75bps of WACC moves fair value by ≈$16.88/share (9%). Rate path and the equity risk premium are the single biggest swing factor.
- **Terminal growth:** 50bps of perpetuity growth is worth ≈$5.11/share — the market's read on the company's long-run competitive position.
- **Operating margin:** each 100bps of EBIT margin across the forecast is worth ≈$3.31/share — watch pricing power, mix and cost discipline in quarterly prints.
- **Top-line delivery:** our base assumes 156.8% year-one growth fading to 2.5%; sustained beats/misses versus that glide path are the cleanest re-rating trigger either way.

Key risks

- Estimate risk: consensus forecasts can be revised sharply, and the forward-multiple lenses move one-for-one with the earnings they are applied to.
- Multiple risk: target multiples are anchored on sector medians; a de-rating of the peer group lowers the target regardless of company performance.
- Single third-party data source: restatements, non-recurring items or classification differences can shift the output.

How big are the risks?

Translating the risks into the DCF: revenue growth −20% (relative) would move the value by -20%; WACC +100bps would move the value by -10%; capex +5pts of revenue would move the value by -5%. These are single-factor shocks; in practice they arrive together (a de-rating and an estimate cut usually do), so the combined effect is larger than any one of them.

What we would monitor

- Delivery against the FY2027 revenue and EPS path in quarterly results, the cleanest re-rating trigger either way.
- The EBIT margin, and whether pricing, mix and cost discipline hold it near the level the DCF assumes.
- The Reloj's phase and probabilities, monthly: a move of the leading phase changes the sector's historical tilt.
- Changes to the cost of equity: rates and the equity risk premium are the single largest swing factor in the DCF.

EXHIBIT 58 FACTOR EXPOSURE

FACTOR	EXPOSURE
Interest rates / discount rate	HIGH
Economic cycle / demand	HIGH
Inflation / input costs	LOW
Credit & refinancing	LOW
Competitive erosion	LOW
Execution vs expectations	LOW
Capital intensity	MEDIUM
Pricing power / margin stability	HIGH

APPENDIX B

Methodology, definitions and disclosures

Method in one paragraph

The price target triangulates relative lenses (target multiples on consensus forward numbers, anchored on peers or a sector reference table and adjusted for durable growth, leverage and earnings durability), a 10-year DCF (consensus for the near years, geometric growth decay, mean-reverting margins) and sector models (residual income, justified P/B, FFO/AFFO, dividends, mid-cycle EBITDA), weighted by company profile. Fair value is rolled forward at the cost of equity and reduced by dividends to give a 12-month target.

Guardrails

A lens outside 0.2×–5× the share price is excluded; a lens more than 2.2× away from the median of the others is down-weighted by 60%; the published target is limited to 0.4×–2.5× the price; fewer than two usable lenses, or a result forced by a guardrail, is published NOT RATED. The Street consensus is anchored at up to 30% (scaled by analyst count; 15% when the count is unknown) and is always shown separately.

Rating bands

On the 12-month expected total return: OVERWEIGHT above +15%, ADD +5% to +15%, NEUTRAL −5% to +5%, REDUCE −15% to −5%, UNDERWEIGHT below −15%.

Scorecard scales

Valuation: expected return −30% to +50% mapped to 0–100. Growth: durable EPS growth 0–25% and FY+1 revenue −5% to +30%. Profitability: ROIC − WACC from −5 to +25 points and EBIT margin 0–35%. Earnings quality: Piotroski share of tests passed, OCF/net income 0.5–1.2 and accruals. Balance sheet: net debt/EBITDA, interest cover and Altman zone. Cycle fit: Reloj tilt −4 to +4 pp a year.

Quality screens

Piotroski F: nine binary tests of profitability, leverage/liquidity and efficiency; tests that cannot be computed from the available statement lines are excluded, not failed. Altman Z (original industrial form): above 2.99 safe, 1.81–2.99 grey, below 1.81 distress. Sloan accruals: (net income − operating cash flow) ÷ average assets.

Reloj de inversión

Phase probabilities and sector evidence come from the Reloj de inversión project's published data (github.com/Perez849/reloj-inversion). Tilt = Σ phase probability × shrunk excess return of the sector in that phase. It describes historical behaviour and is not an input to the price target.

Data and limits

Fundamentals and consensus come from Yahoo snapshot as of 2026-07-08; the company was classified as **Standard (forward multiples + DCF)**. Forward numbers are analyst consensus where available and reported figures otherwise. A single third-party source can contain restatements, one-off items or classification differences that move the output; the model flags what it can detect and refuses to publish a number it cannot defend.

Definitions

EV: enterprise value = market capitalisation + net debt + minorities. NTM: next twelve months, a time-weighted blend of the two nearest forecast fiscal years. FCFF: free cash flow to the firm = NOPAT + D&A − capex − change in working capital. WACC: weighted average cost of capital. ROIC: NOPAT ÷ invested capital (debt + equity − cash). PEG: P/E ÷ durable earnings growth. Tilt: probability-weighted excess return of a sector against the US market, in percentage points a year.

Disclaimer

This research note is generated by an automated, sector-aware valuation engine from public data. It is an analytical tool, not investment advice, a recommendation or an offer to transact, and it is no substitute for fundamental judgement. Past performance and historical sector behaviour are not guides to future returns. Do your own due diligence.
